

1) Average Engagement Rate

Avg Engagement Rate =

AVERAGE (clean_data[engagement_rate])

Simple meaning:

This shows the **average engagement rate across all posts**.

Why it matters:

Engagement rate tells how interesting the content is, not just how many people saw it.

In one line:

On average, this percentage of users interact with a post.

2) Average Reach

Avg Reach =

AVERAGE (clean_data[reach])

Simple meaning:

This shows how many **unique users are reached by a post on average**.

Why it matters:

It helps understand content visibility.

3) Engagement Efficiency

Engagement Efficiency =

DIVIDE(
 [Avg Engagement Rate],
 [Avg Reach]
)

Simple meaning:

This shows **how much engagement we get per unit of reach**.

Why it matters:

It helps compare content performance fairly, even if reach is different.

In one line:

High efficiency means content performs well even with lower reach.

4) Engagement Rate

Engagement Rate =

DIVIDE(
 [Total Engagement],
 SUM('clean_data'[impressions])
)

Simple meaning:

This calculates engagement as a percentage of impressions.

Why it matters:

It shows how many people interact after seeing the post.

5) Total Engagement

Total Engagement =

SUM('clean_data'[likes]) +
SUM('clean_data'[comments]) +
SUM('clean_data'[shares]) +
SUM('clean_data'[saves])

Simple meaning:

This adds up **all user interactions** on posts.

Why it matters:

It shows overall audience activity.

6) Total Followers Gained

Total Followers Gained =

SUM (clean_data[followers_gained])

Simple meaning:

This shows how many **new followers were gained from all posts**.

Why it matters:

It directly connects content performance to growth.

7) Total Impressions

Total Impressions =

SUM('clean_data'[impressions])

Simple meaning:

This shows how many times posts were **displayed to users**.

Why it matters:

It measures content exposure.

8) Total Posts

Total Posts =

```
COUNT ( clean_data[post_id] )
```

Simple meaning:

This counts the **total number of posts analyzed**.

Why it matters:

It provides scale and context for analysis.

9) Total Reach

Total Reach =

```
SUM('clean_data'[reach])
```

Simple meaning:

This shows the **total number of unique users reached** across all posts.

Why it matters:

It shows how wide the content distribution is.

10) Viral Post Percentage

Viral Post % =

```
DIVIDE(  
    CALCULATE(  
        COUNT('clean_data'[post_id]),  
        'clean_data'[performance_bucket_label] = "viral"  
    ),  
    COUNT('clean_data'[post_id])  
)
```

Simple meaning:

This shows **what percentage of posts became viral**.

Why it matters:

It helps understand how often content performs exceptionally well.

11) Viral Rate

Viral Rate =

```
DIVIDE (
    CALCULATE (
        COUNT ( clean_data[post_id] ),
        clean_data[performance_bucket_label] = "viral"
    ),
    COUNT ( clean_data[post_id] )
)
```

Simple meaning:

This is another way of calculating **viral percentage**.

Why it matters:

It confirms consistency in viral performance measurement.

✦ *Note:*

Both **Viral Post %** and **Viral Rate** calculate the same metric. You can keep **one** to avoid redundancy.

Simple Summary (Use in Interview)

"I used DAX measures to calculate engagement, reach, growth, and virality metrics dynamically, allowing the dashboard to update instantly based on filters like media type, time period, and account type."
